## EQUIVALENCE CONCEPTS

Equivalence Relations are a very important aspect of algebraic specification techniques.

> In other techniques (such as EFSM-based) we don't have such extensive theory of equivalence.

Although proving equivalence of real-life specs is impossible with today's means, a theory of equivalence is important for:

- precise understanding of language semantics
- tool development: tools may use the fact that some expressions are equivalent: e.g. A[] $\mathrm{B}=\mathrm{B}[] \mathrm{A}$
- correctness-preserving transformation: transforming a specification written to emphasize certain aspects into a specification written to emphasize others

# Equivalence-preserving transformations and Software Design 

Design can start with a very abstract specification, representing the requirements.

Then, using equivalence-preserving transformations, this specification can be gradually transformed into an an implementation-oriented specification.

Finally, this one can be transformed into code.
Maintenance may require to replace some components with others, while maintaining the same system behavior.

Other equivalence-preserving transformation can make it possible to obtain various types of test cases (functional, blackbox, white-box, etc.) from the specifications.

Tools to help in this process are available.
There is a lot of research in this area...

## When are two processes EQUIVALENT?

## Some possibilities:

- whenever they can engage in identical action sequences (traces)
- whenever they have the same observable behavior (bisimulation)
- whenever no tester can distinguish them (testing equivalence)
- whenever they can be replaced one for the other in any system, yielding equivalent systems (congruences)
- whenever they have the same behavior trees (equality)

## All these concepts will be examined in the course.

## Others have been considered in the literature.

EQUIVALENT?

## TRACE EQUIVALENCE

Perhaps the simplest possible equivalence concept:

A trace is a sequence of observable actions
Two processes are trace equivalent (tr)
iff they can engage in the same traces
$B=s=>$, where $s$ is a trace, means that $B$ can engage in s, i.e. $\exists \mathrm{B}$ ' s.th. B leads to $\mathrm{B}^{\prime}$ after the observable sequence $s$, so

$$
\mathrm{B} 1 \operatorname{tr} \mathrm{~B} 2 \text { iff } \forall \mathrm{s}, \mathrm{~B} 1=\mathrm{s}=>\text { iff } \mathrm{B} 2=\mathrm{s}=>
$$

three 'trace equivalent' processes
Traces: $\{\varepsilon, \mathrm{a}, \mathrm{ab}, \mathrm{ac}\}$
NB: the empty trace $\varepsilon$ is always included (note that empty trace does not mean internal action)

## IDENTITY $=($ ALSO $\equiv)$

Behavior expressions have identical beh. trees (incl. all internal and external actions)

The expansion laws are the best known identities.

To be discussed.

We can conclude

$$
\mathrm{M} \sim \mathrm{M}^{\prime}
$$

## BISIMULATION

Informally, it is reasonable to think that two b.exp. are equivalent if, whenever one of them can execute some action(s) leading to some behavior $B$, the other can execute the same action(s) leading to a behavior $\mathrm{B}^{\prime}$, where B is again equivalent to B '.

This is the basic idea of bisimulation: an inductive concept.

For two labelled transition systems S and S', we write
S -a -> S' (a: internal or external)
if $S$ can execute action a and become $S^{\prime}$

## STRONG BISIMULATION $\ominus$

A relation $\mathfrak{R}$ over LTS is a strong B. iff $\left.\forall<s_{1}, s_{2}\right\rangle$
$\in \mathfrak{R}, \forall$ actions a (internal or external)

1) if $\exists s_{1}{ }^{\prime}$ s.th. $s_{1}-a->s_{1}{ }^{\prime}$ then $\exists s_{2}$ ' s.th. $s_{2}-$

$$
\text { a }->\mathrm{s}_{2}^{\prime} \text { and }\left\langle\mathrm{s}_{1}{ }^{\prime}, \mathrm{s}_{2}{ }^{\prime}\right\rangle \in \mathfrak{R}
$$

2 ) and vice-versa (interchange $s_{1}$ and $s_{2}$ )

Strongly Bisimilar LTS must be able to execute the same actions, and if they execute identical actions they must transform into strongly bisimilar LTS.

There is a strong bisimulation between:

But not between:

Nor between:

$\mathrm{A} \sim$ law which is not $\mathrm{a}=$ law:

> B [] B ~B

In this case, the relation $\mathfrak{R}$ is:
\{ <a;b;stop [] c;stop, a;b;stop [] a;b;stop [] c;stop>\} U Id where Id is the set of all identical behavior pairs

## In fact:

$$
\begin{aligned}
& \text { a;b;stop [] c;stop - a -> b;stop } \\
& \text { a;b;stop [] a;b;stop [] c;stop -a -> b;stop }
\end{aligned}
$$

and $\langle\mathrm{b} ; \mathbf{s t o p}, \mathrm{b} ; \boldsymbol{s t o p}\rangle \in \mathrm{Id}$
Also

$$
\begin{aligned}
& \text { a;b;stop [] c;stop - c -> stop } \\
& \text { a;b;stop [] a;b;stop [] c;stop -c -> stop }
\end{aligned}
$$

and $<$ stop, stop> $\in$ Id
This is symmetric because on the right there are no additional transitions.

A STRONG BISIMULATION

Strong bisimulation is fairly easy to compute, hence this relation is commonly used in tools to simplify LTSs.

# ABSTRACTING FROM i (to some extent) 

i) Let $s$ denote a string of actions, $s=a_{1} \ldots a_{n}$
we write $\mathrm{B}-\mathrm{s}->\mathrm{B}$ ' iff
$\exists B_{1} \ldots B_{n}$ s.th. $B-a_{1}->B_{1} \ldots B_{n-1}-a_{n}->B_{n}=B$,
we also write $B-\varepsilon->B$, where $\varepsilon=$ empty string
ii) Let $s$ denote a string of observable actions, $s=a_{1} \ldots a_{n}$, and let $i^{k}$ be a string of $k$ internal actions
we write $\mathrm{B}=\mathrm{s}=>\mathrm{B}$ ' whenever

$$
\exists i^{k_{0}} a_{1} i^{k_{1}} a_{2} \ldots a_{n}{ }^{k_{n}}
$$

( s with an arbitrary number of i interspersed) s.th.

$$
B-i^{k_{0}} a_{1} i^{k_{1}} a_{2} \ldots a_{n}{ }^{k_{n}} \rightarrow B^{\prime}
$$

## EXAMPLES:

## Given a path on a LTS

$$
\mathrm{B}_{0}-\mathrm{i}->\mathrm{B}_{1}-\mathrm{a}->\mathrm{B}_{2}-\mathrm{i}->\mathrm{B}_{3}-\mathrm{b}->\mathrm{B}_{4}
$$

we may write

$$
\begin{aligned}
& \mathrm{B}_{0}-\mathrm{i} \text { a ib }->\mathrm{B}_{4} \\
& \mathrm{~B}_{0}=\mathrm{ab} \Rightarrow \mathrm{~B}_{4} \\
& \mathrm{~B}_{1}=\mathrm{a} \Rightarrow>\mathrm{B}_{2} \\
& \mathrm{~B}_{0}=\varepsilon \Rightarrow \mathrm{B}_{1} \\
& \mathrm{~B}_{0}=\varepsilon \Rightarrow \mathrm{B}_{0} \\
& \mathrm{~B}_{0}=\mathrm{a} \Rightarrow \mathrm{~B}_{2} \\
& \mathrm{~B}_{0}=\mathrm{a} \Rightarrow \mathrm{~B}_{3}
\end{aligned}
$$

etc.

Based on the observable sequence relation, we define a notion of weak bisimulation.

## Definition

A relation $\Re$ between LTS is a weak bisimulation if for any pair <B1, B2> in $\mathfrak{R}$ and for any string $s$ of observable actions:
whenever $B_{1}=s=>B_{1}{ }^{\prime}$, then for some $B_{2}{ }^{\prime}$ :

$$
\mathrm{B}_{2}=\mathrm{s}=>\mathrm{B}_{2}^{\prime} \text { and } \mathrm{B}_{1}^{\prime}{ }^{\prime} \mathfrak{R} \mathrm{B}_{2}^{\prime}
$$

whenever $B_{2}=s=>B_{2}{ }^{\prime}$, then for some $B_{1}{ }^{\prime}$ :

$$
\mathrm{B}_{1}=\mathrm{s} \Rightarrow \mathrm{~B}_{1}^{\prime} \text { and } \mathrm{B}_{1}{ }^{\prime} \mathfrak{R} \mathrm{B}_{2}{ }^{\prime}
$$

The idea of weak bisimulation is that two bisimilar LTS must be able to simulate each other, in terms of observable sequences, and then reach bisimilar LTS.

## Definition

Two LTS $\mathrm{B}_{1}$ and $\mathrm{B}_{2}$ are weak bisimulation equivalent or observationally equivalent $\left(\mathrm{B}_{1} \approx \mathrm{~B}_{2}\right)$ if there exists a weak bisimulation $\mathfrak{R}$ which contains the pair $\left\langle\mathrm{B}_{1}, \mathrm{~B}_{2}\right\rangle$.

Note that a ai aii on the lhs go respectively to identical subrees as the three a alternatives on the rhs

# BASIC LAW of O.E.: i;B $\approx$ B 

Basic case where $\mathrm{B}_{1} / \approx \mathrm{B}_{2}$

Note:

$$
\begin{array}{lll}
\mathrm{B}_{1}=\varepsilon \Rightarrow & \stackrel{0}{0} & \mathrm{~B}_{1} \\
& \mathrm{~B}_{2}=\varepsilon \Rightarrow & \stackrel{\mathrm{b}}{6} \\
\hdashline & \mathrm{~B}_{2}
\end{array}
$$

Obviously $\mathrm{B}_{1}{ }^{\prime}$ does not bisimulate $\mathrm{B}_{2}{ }^{\prime}$ because $B_{2}=b=>$ stop while the same thing is false for $\mathrm{B}_{1}{ }^{\prime}$.

In some sense, observation equivalence can be considered too strong as it distinguishes between behavior trees that can be said to behave the same way externally (see trees III and VIII). For this reason, its name may be inappropriate.

However, o.e. has some desirable formal properties (in particular, it is defined inductively), so it is appropriate for formal reasoning.

Unfortunately, it is expensive to compute (it requires unbounded recursive descent in the LTS, while keeping track of $\mathfrak{R}$ ) so it is not often used in tools to simplify LTS.

Also, we shall now see another meaning of equivalence for which o.e. is in fact too weak...

## CONTEXTS

# A context $\mathrm{C}[\bullet]$ is a behavior expression containing one or more occurrences of the special process variable [॰] (the hole). 

If $B$ is a $b$. expr. then $C[B]$ denotes the result of replacing $[\bullet]$ by B in context $\mathrm{C}[\bullet]$.

Note then that 'the hole' represents a behavior expression, or, if we are talking about behavior trees, a whole behavior tree (from the root).

## Observational Congruence

Two behaviours are observationally congruent when they can be interchanged one for the other in any behaviour expression, yielding observationally equivalent behaviour expressions.

## More Formally:

Two b.exp. $\mathrm{B}_{1}$ and $\mathrm{B}_{2}$ are observationally congruent $\mathrm{B}_{1} \approx{ }^{\mathrm{c}} \mathrm{B}_{2}$ iff for all contexts $\mathrm{C}[\bullet]$, $\mathrm{C}\left[\mathrm{B}_{1}\right] \approx \mathrm{C}\left[\mathrm{B}_{2}\right]$.

## Some Laws of Observation Equivalence and Congruence

Let $C$ be a LOTOS context of the form
$\mathrm{a} ;[\boldsymbol{\bullet}]$
$[\bullet]|[\mathrm{A}]| \mathrm{B}$ or $\mathrm{B}|[\mathrm{A}]|[\bullet]$
for these contexts

$$
\approx, \approx^{c}
$$

$[\bullet] \gg B$ or $B \gg[\bullet]$
$[\bullet][>B$ B are the same

Then $\mathrm{B}_{1} \approx \mathrm{~B}_{2}$ implies $\mathrm{C}\left[\mathrm{B}_{1}\right] \approx \mathrm{C}\left[\mathrm{B}_{2}\right]$
However in context a; stop [] [•]

$$
\mathrm{b} ; \text { stop } \approx \mathbf{i} ; \mathrm{b} ; \mathbf{s t o p}
$$

But a;stop[]b;stop $/ \approx$ a; stop [] i;b;stop (the devil can act only if there is a choice!)
and similarly for context $\mathrm{B}[>[\bullet]$
(proof techniques to be discussed later)

# Some Laws of Observational Congruence 

## Formal concepts of implementation: the intuitive basis (C.A.R.Hoare)

Suppose you have specified that you want a machine which

- always gives you coffee when you ask for it,
- but it may or may not give you tea (= can deadlock on tea, can refuse tea).

You must accept a machine which is only able to give you coffee!

This is because if you keep asking for tea, and not getting it, the maker can argue that this is consistent with your specification.

In LOTOS terms, the presence of internal actions in choices can be taken to represent implementation options.

Note that this reasoning breaks down in the presence of time constraints, which has interesting consequences for timed process algebras.

# (non-symmetric) <br> RELATION red MODELS IMPLEMENTATION in the sense of taking away unnecessary options <br> <br> I red $\mathrm{S}=(\mathrm{I}$ implements S$)$ 

 <br> <br> I red $\mathrm{S}=(\mathrm{I}$ implements S$)$}

I can only execute actions that $S$ can.
I can only refuse actions that $S$ can.
E.g.

Bred i;B [] i;C
C red $\mathbf{i} ; \mathrm{B}[] \mathbf{i} ; \mathrm{C}$
Bredi;B [] C
note: C red $\mathbf{i} ; \mathrm{B}[] \mathrm{C}$ is false
$\mathrm{a} ;(\mathrm{B} 1[] \mathrm{B} 2)$ red $\mathrm{a} ; \mathrm{B} 1[] \mathrm{a} ; \mathrm{B} 2$
note: converse is false
$\mathrm{a} ; \mathrm{B} 1$ red $\mathrm{a} ; \mathrm{B} 1[] \mathrm{a} ; \mathrm{B} 2$

I te $\mathrm{J}=(\mathrm{I}$ is testing equivalent to J$)=_{\text {def }}$
I red J and J red I

We will see that

$$
=\subset \sim \subset \approx^{\mathrm{c}} \subset \approx \subset t e \subset t r
$$

Also we will see that on the basis of these equivalence relations it is possible to

- define concepts of conformance and
- give algorithms for generating test suites to test whether an implementation conforms to a specification

## Concepts discussed in Class 4:

- Importance of the concept of behavioral equivalence
- Why do we have several versions of this concept
- The most important equivalence concepts were introduced briefly
- Trace equivalence
-• Identity or equality
- Strong Bisimulation
-• Weak bisimulation or Observation equival.
-• Observation congruence
-• Reduction and testing equivalence
Will be discussed in detail...
